

A Little More Advanced Biotechnology Tools

Better Plasmids

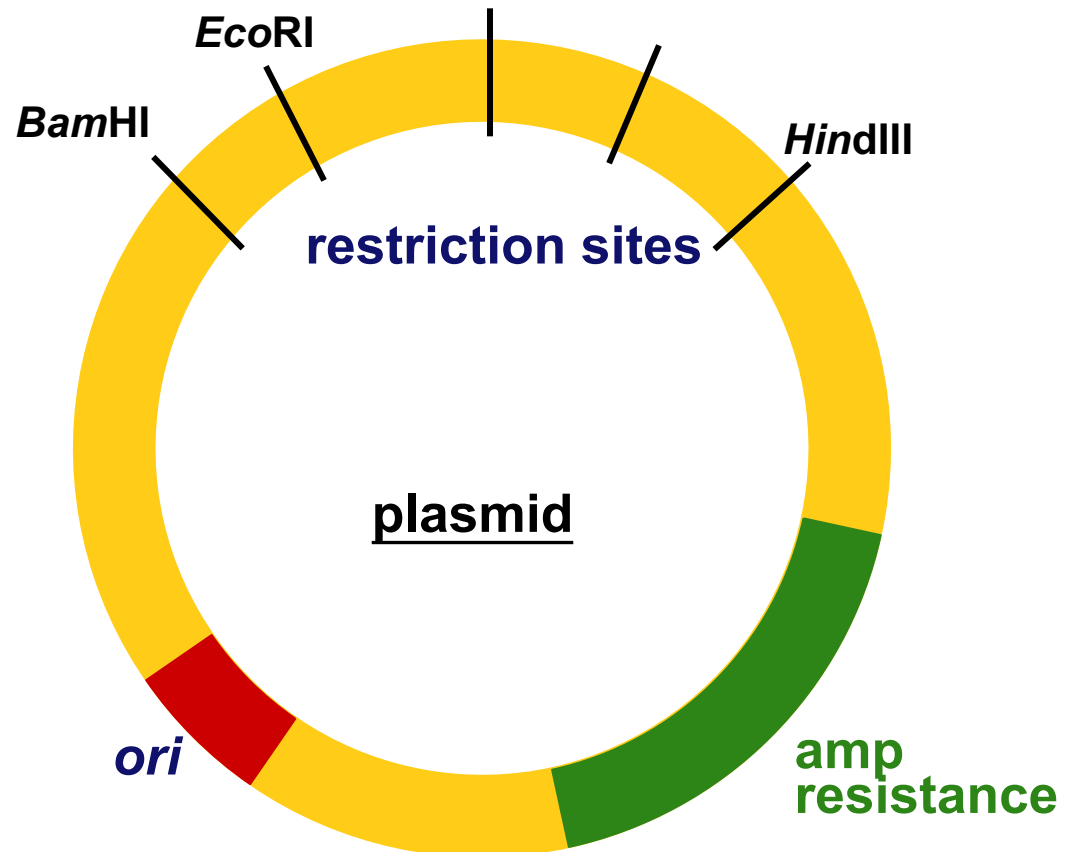

Engineered plasmids

- Building custom plasmids
 - ◆ restriction enzyme sites
 - ◆ antibiotic resistance genes as a selectable marker

Selectable marker

- antibiotic resistance gene on plasmid
 - § ampicillin resistance
- selecting for successful transformation
 - § successful uptake of recombinant plasmid

Selection for plasmid uptake

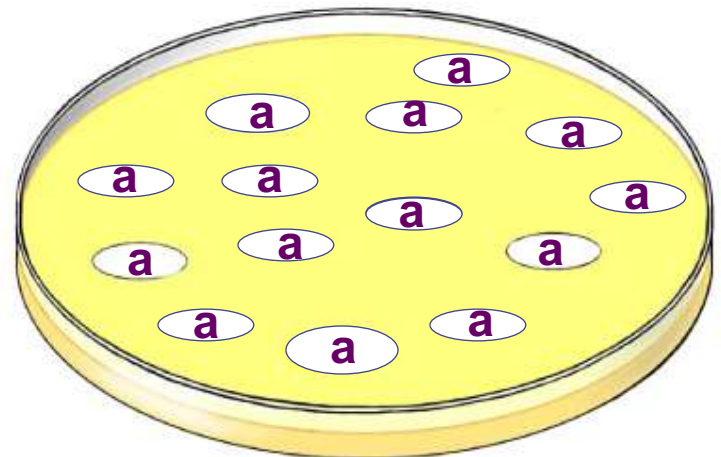

- Antibiotic becomes a **selecting agent**
 - only bacteria with the plasmid will grow on antibiotic (**ampicillin**) plate

all bacteria grow

LB plate

only **transformed** bacteria grow

LB/*amp* plate

cloning

Need to screen plasmids

- Need to make sure bacteria have recombinant plasmid

Screening for recombinant plasmid

- Bacteria take up plasmid
- Functional LacZ gene
- Bacteria make blue color

- Bacteria take up recombinant plasmid
 - Non-functional LacZ gene
 - Bacteria stay white color

Which colonies do we want?

Finding your “Gene of Interest”

Finding your gene of interest

■ DNA hybridization

- ◆ find sequence of DNA using a labeled
 - short, single stranded DNA molecule
 - complementary to part of gene of interest
 - labeled with radioactive P^{32} or fluorescent
- ◆ heat treat DNA in gel
 - unwinds (denatures) strands
- ◆ wash gel with probe
 - probe hybridizes with denatured DNA

genomic DNA

AP Biology

Southern blotting

restriction digest

gel electrophoresis

blot DNA off of gel onto filter paper

wash filter with labeled probe

AP Biology

expose filter paper to X-ray film

Edwin Southern

Southern blotting

gel of genomic DNA

Southern blot IDing one gene

Southern blot illustration

DNA libraries

- **Cut up all of nuclear DNA from many cells of an organism**
 - ◆ restriction enzyme
- **Clone all fragments into many plasmids at same time**
 - ◆ “shotgun” cloning
- **Create a stored collection of DNA fragments**
 - ◆ petri dish has a collection of all DNA fragments from the organism

Making a DNA library

1 all DNA from many cells of an organism is cut with restriction enzymes

2 engineered plasmid with selectable marker & screening system

3 all DNA fragments inserted into many plasmids

4 clone plasmids into bacteria

DNA library

recombinant plasmids
inserted into bacteria

gene of interest

But how
do we find
colony with our
gene of interest
in it?

DNA Library

plate of bacterial colonies
storing & copying all genes
from an organism (ex. human)

Find your gene in DNA library

▪ Locate Gene of Interest

◆ to find your gene you need some of gene's sequence

▪ if you know sequence of protein...

◆ can “guess” part of DNA sequence

◆ “back translate” protein to DNA

▪ if you have sequence of similar gene from another organism...

◆ use part of this sequence

Which
bacterial colony
has our gene?
Like a needle
in a haystack!

Colony Blots

1

Cloning

- plate with bacterial colonies carrying recombinant plasmids

4

Locate

- expose film
- locate colony on plate from film

plate

plate + filter

film

2

Replicate plate

- press filter paper onto plate to take sample of cells from every colony

3

Hybridization

- heat filter paper to denature DNA
- wash filter paper with radioactive probe which will only attach to gene of interest

filter

Problems...

- **Human Genome library**
 - ◆ are there only genes in there?
 - ◆ nope! a lot of junk!
 - ◆ human genomic library has more “junk” than genes in it
- **Clean up the junk!**
 - ◆ if you want to clone a human gene into bacteria, you can't have... **introns**

How do you clean up the junk?

- Don't start with DNA...
- Use mRNA
 - ◆ copy of the gene without the junk!
- But in the end, you need DNA to clone into plasmid...
- How do you go from RNA → DNA?
 - ◆ reverse transcriptase from RNA viruses

cDNA (copy DNA) libraries

- Collection of only the coding sequences of expressed genes
 - extract mRNA from cells
 - reverse transcriptase**
 - RNA → DNA
 - from **retroviruses**
 - clone into plasmid
- Applications
 - need edited DNA for expression in bacteria
 - human insulin

Where do we go next....

DNA → **RNA** → **protein** → **trait**

- **When a gene is turned on, it creates a trait**
 - ◆ **want to know what gene is being expressed**

extract mRNA from cells
mRNA = active genes

How do you match mRNA back to DNA in cells???

reverse transcriptase

Microarrays

slide with spots of DNA
each spot = 1 gene

- Create a slide with a sample of each gene from the organism
 - ◆ each spot is one gene
- Convert mRNA → labeled cDNA

mRNA → cDNA

mRNA from cells

Microarrays

slide with spots of DNA
each spot = 1 gene

- Labeled cDNA hybridizes with DNA on slide
 - ◆ each **yellow** spot = gene matched to mRNA
 - ◆ each **yellow** spot = expressed gene

mRNA → cDNA

cDNA matched to genomic DNA

Application of Microarrays “DNA Chip”

2-color fluorescent tagging

- **Comparing treatments or conditions = Measuring change in gene expression**
- **sick vs. healthy; cancer vs. normal cells**
 - ◆ before vs. after treatment with drug
 - ◆ different stages in development
 - ◆ **Color coding: label each condition with different color**
- **red = gene expression in one sample**
 - ◆ **green = gene expression in other sample**
 - ◆ **yellow = gene expression in both samples**

I may be very selective...
But still Ask Questions!
