

# DNA and RNA

## Replication, Transcription and Translation

# SB2b

□ Students will analyze how biological traits are passed on to successive generations.

b. Explain the role of DNA in storing and transmitting cellular information

---

# Essential Question

- What is the role of DNA in the process of passing biological traits from one generation to the next?

# What is DNA?

- Deoxyribonucleic Acid
- Genetic Information
- Stores and transmits all genetic information needed for the existence of living organisms
- Each cell in a multicellular organism has the same exact copy of DNA

# What is RNA?

- Ribonucleic Acid
- Single strand
- Job – Read the DNA
- RNA carries out the work of DNA
  - DNA is the blueprint
  - RNA is the Contractor/Builders

## Structure of RNA

# Types of RNA

- mRNA goes into the nucleus and gets the message from DNA
  - Codon
  - Single stranded
- rRNA reads (translates) the mRNA so the DNA command can be carried out
- tRNA gets the message from rRNA and obtains the necessary parts
  - Anticodon
  - Bring AA to Ribosomes for protein assembly

# Structure of Molecules

## □ DNA

- Deoxyribose – 5 carbon sugar
- Phosphate
- Nitrogen base

## □ RNA

- Ribose – 5 carbon sugar
- Phosphate
- Nitrogen Bases

# Complementary Base Pairing

- DNA has two sides or strands. We say that one strand is complementary to the other, meaning that they use Chargaff's base pairing rule to match up.
- Chargaff's rule states that:
  - Adenine always pairs with thymine (A-T) &
  - In RNA, adenine always pairs with uracil (A-U)
  - Cytosine always pairs with guanine (C-G)
- The two strands of DNA are held together by hydrogen bonds.

# REPLICATION

# Replication of DNA

- DNA has to copy itself because when new cells are made, the cell has to have an exact copy of the DNA.
- This occurs during the cell cycle in the S phase.
- This process is called Replication
  - It is considered semiconservative

# Replication continued

- Replication begins with DNA untwisting itself and opening up
  - DNA Helicase
    - Responsible for unwinding the molecule
- The old DNA strands = templates
- New nucleotides come and bond to the template creating a new strand = Complementary Strand
  - DNA Polymerase 
    - Responsible for adding nucleotides
    - Forms covalent bond between nucleotides
  - DNA ligase binds the two new strands

# Replication continued

□ DNA is read in parts

■ It does not start at the beginning and go all the way to the end, that would take too long

□ Replication can start at many points in eukaryotes

There are many origins of replication in eukaryotic chromosomes.

# Replication continued

- DNA is “proof read” by enzymes
  - The enzymes fix any mistakes
    - DNA polymerase
  - Mistakes not fixed will cause problems
    - We will discuss the problems when we get to human genetics

# Practice Replication

■ TTGCTAG

■ TAGCGCT

■ ACCGTCA

■ GCTATGT

# Central Dogma

# Central Dogma

- The central dogma states that information flows in one direction from DNA to RNA to proteins.

# TRANSCRIPTION

# Transcription

- Transcription is the **process of mRNA copying DNA**
  - This is how **new mRNA is made**
  - Copies a gene and can make many copies
- This **occurs in the nucleus**
- Occurs just **like replication but with RNA instead**
  - Only **one side of the DNA is copied**
  - Enzyme – RNA Polymerase 

# Transcription

- **Operon** – the “switch” to turn on/off transcription
- **Promoter** – DNA site that promotes RNA polymerase to bind
- **Repressor** – molecule that binds to DNA to block transcription
- **Inducer** – molecule that takes repressor away

# Practice Transcription

□ T T G C T A G

□ T A G C G C T

□ A C C G T C A

□ G C T A T G T

# Transcription

# TRANSLATION

# Translation

- a/k/a Protein Synthesis
- DNA is ultimately a code for protein production
- Proteins in turn make up all the parts of cells which will then control all chemical processes
- Proteins are made up of Amino Acids

# Translation

1. mRNA transcribes the DNA (gets the message/code)
2. mRNA carries the message from the nucleus to the ribosomes (on the ER)
3. rRNA inside the ribosomes reads the mRNA

---

# Translation continued

4. rRNA tells tRNA which Amino Acids are needed
5. tRNA collects and brings back the Amino Acids
6. rRNA hooks together the Amino Acids into a protein

# Codons

- Every 3 nitrogen bases on the mRNA = Codon
  - A codon is a code for an Amino Acid or start and stop codons.
    - Start Codon: AUG (needed for process to begin)
    - Stop Codons: UAA, UGA, UAG
- On the tRNA is an anticodon – it is complementary to the codon
- Example: Codon UUU, Anticodon AAA
- Practice: Codon CGC, Anticodon

The genetic code matches each RNA **codon** with its amino acid or function.

		Second base									
		U		C		2 A		G			
First base	U	UUU	phenylalanine (Phe)	UCU	serine (Ser)	UAU	tyrosine (Tyr)	UGU	cysteine (Cys)	U	
		UUC		UCC			UAC		UGC		C
		UUA	leucine (Leu)	UCA			UAA	STOP	UGA	STOP	A
		UUG		UCG			UAG	STOP	UGG	tryptophan (Trp)	G
	1 C	CUU	leucine (Leu)	CCU	proline (Pro)	CAU	histidine	CGU	arginine (Arg)	U	
		CUC		CCC		CAC	(His)	CGC		C	
		CUA		CCA		CAA	glutamine (Gln)	CGA		A	
		CUG		CCG		CAG		CGG		G	
	A	AUU	isoleucine (Ile)	ACU	threonine (Thr)	AAU	asparagine (Asn)	AGU	serine (Ser)	U	
		AUC		ACC		AAC		AGC	C		
		AUA		ACA		AAA	lysine (Lys)	AGA	A		
		AUG	methionine (Met)	ACG	AAG		AGG	arginine (Arg)	G		
G	GUU	valine (Val)	GCU	alanine (Ala)	GAU	aspartic acid (Asp)	GGU	glycine (Gly)	U		
	GUC		GCC		GAC		GGC		C		
	GUA		GCA		GAA	glutamic acid (Glu)	GGA		A		
	GUG		GCG		GAG		GGG		G		
								Third base			

- Find the first base, C, in the left column.
- Find the second base, A, in the top row. Find the box where these two intersect.
- Find the third base, U, in the right column. CAU codes for histidine, abbreviated as His.

**Translation** converts an mRNA transcript into a polypeptide.  
The process consists of three repeating steps.

Translation occurs in the cytoplasm of both eukaryotic (illustrated) and prokaryotic cells. It starts when a tRNA carrying a methionine attaches to a start codon.

**1**

The exposed codon in the first site attracts a complementary tRNA bearing an amino acid. The tRNA anticodon pairs with the mRNA codon, bringing it very close to the other tRNA molecule.

**2**

The ribosome forms a peptide bond between the two amino acids and breaks the bond between the first tRNA and its amino acid.
