

SAT® Suite of Assessments Administration Report

Delaware
SAT® School Day Administration
March 2020

Executive Summary

This report summarizes the performance of 9,233 11th and 12th grade Delaware test takers who took the March 2020 SAT® School Day administration. There were five master forms administered in Delaware (form 1 had 2,077 test takers; form 2 had 2,066 test takers; form 3 had 2,049 test takers; form 4 had 2,091 test takers; form 5 had 950 test takers). This report provides an analysis of the quality of the test forms administered to at least 100 test takers in the state of Delaware. Psychometric and statistical summaries related to the moments, intercorrelations, reliability and standard error of measurement (SEM), item completion rates, form speededness, differential item functioning, and classification accuracy and consistency are also included. Depending on psychometric recommendations for minimum sample sizes for these analyses, results are reported only for forms for which the subgroup sample size was 5 or more, 100 or more, or 200 or more.

This report also summarizes the performance of 8,827 students who took the SAT Essay in the March 2020 School Day administration and received non-zero scores. This report includes a summary of descriptive statistics, frequency distributions, correlations of essay dimension scores, and interrater consistency.

Quality of the form(s):

Most of the test takers included in this sample were 11th graders. About 82% spoke English or English and another language as their first language. About 49% of the sample was male and 51% was female.

The range of the mean Evidence-Based Reading and Writing (ERW) score was 414 to 491 across forms and the range of the standard deviations was 89 to 100. The range in mean Math Section score (MSS) across forms was 402 to 480, with a range in standard deviation of 88 to 101. The range of the mean total scores was 816 to 970 across forms and the range of the standard deviation was 167 to 190.

The average observed score correlation between ERW and MSS across forms was 0.79. The range in observed score correlations between ERW scores and MSS scores across forms was 0.76 to 0.81. The average true score correlation between ERW and MSS across forms was 0.87. The range in ERW/MSS true score correlations across forms was 0.85 to 0.88.

The average scale score reliability of ERW across forms was 0.93. The range in scale score reliability of ERW across forms was 0.93 to 0.94. The average conditional standard error of measurement (CSEM) for ERW across forms was 25. The range in CSEM for ERW across forms was 24 to 25. The average scale score reliability of MSS was 0.89. The range in scale score reliability of MSS across forms was 0.86 to 0.90. The average CSEM for MSS was 32. The range in CSEM for MSS across forms was 31 to 33. The average scale score reliability of the Total score across forms was 0.95. The range in scale score reliability of the Total score across forms was 0.94 to 0.96. The average conditional standard error of measurement (CSEM) for the Total score across forms was 40. The range in CSEM for the Total score across forms was 40 to 41.

Over 95% of the sample completed at least 75% of each of the Reading, Writing and Language, Math – No Calculator, and Math – Calculator timed sections of the test across all forms.

Seven items were classified as showing significant differential item functioning.

The percentage of test takers who met Level 3 and Level 4 for ERW was between 20% and 53%. The percentage of test takers who met Level 3 and 4 for MSS was between 10% and 32%. The probability of correct classification for the total group was between 0.81 and 0.87 for ERW and 0.80 and 0.86 for MSS. The proportion of consistent decisions for the total group was between 0.74 and 0.82 for ERW and between 0.71 and 0.80 for MSS.

About 9,124 test takers took the SAT essay test. Out of these test takers, 8,827 received non-zero essay scores. The average dimension scores were 4.26 for essay reading, 3.25 for essay analysis, and 4.78 for essay writing across all forms.

The observed score correlations of the three essay dimension scores were 0.57 between essay reading and essay analysis, 0.80 between essay reading and essay writing, and 0.67 between essay analysis and essay writing. The range of the correlations between essay dimension scores and Reading Test scores, Writing and Language Test scores and ERW scores was 0.52 to 0.64.

The percentage of exact agreement between the two raters was 66.13 for essay reading, 70.23 for essay analysis, and 70.93 for essay writing. The correlations between the essay dimension scores given by two raters for essay reading were 0.59 with an SEM of 0.44, 0.60 with an SEM of 0.40 for essay analysis, and 0.68 with an SEM of 0.39 for essay writing. The simple Kappa was 0.44 for essay reading, 0.48 for essay analysis, and 0.52 for essay writing. The weighted Kappa was 0.50 for essay reading, 0.53 for essay analysis, and 0.59 for essay writing.

SAT Suite of Assessments

The SAT Suite of Assessments (i.e., SAT®, PSAT/NMSQT®, PSAT™ 10, and PSAT™ 8/9) is designed to measure student readiness for college and postsecondary education. Each assessment contains two sections (Evidence-Based Reading and Writing section [ERW] and the Math section [MSS]), three tests (Reading Test, Writing and Language Test, and Math Test), two cross-tests (Analysis in History/Social Studies and Analysis in Science) and seven subscores (Command of Evidence, Words in Context, Expression of Ideas, Standard English Conventions, Heart of Algebra, Problem Solving and Data Analysis, and Passport to Advanced Math). For the SAT, test takers are given three hours to complete 154 items. Test takers who choose to also take the optional Essay are given an additional 50 minutes.

This report contains summary information about the score tiers; specifically, the total, section, and test scores, as well as the cross-test scores, and the subscores from the March 2020 School Day administration of the SAT forms for the state of Delaware. Raw scores were generated from the number of items the student answered correctly within the score tier. Scale scores were generated by applying the appropriate raw-to-scale score conversions. Table 1 describes the number of items and score scale ranges for the SAT.

The Reading Test and Writing and Language Test are administered in separately-timed sections and only contain multiple-choice (MC) items. The Math Test is administered over two separately-timed sections, Math – No Calculator and Math – Calculator. In addition, the Math Test includes two types of items in each timed section, multiple-choice (MC) items and student-produced response (SPR) items. The SAT also includes an optional essay with one prompt. See Table 2 for the number and type of items per timed section for the included forms. The content specifications for the SAT provide additional details for each test within the SAT and can be found at

<https://collegereadiness.collegeboard.org/pdf/test-specifications-redesigned-sat-1.pdf>.

The content specifications are deeply informed by evidence about essential requirements for college and career readiness and success. In constructing each test form of the SAT, the content specifications are of primary importance. As such, the SAT forms in the Delaware March 2020 School Day administration meet 100% of the target content specifications. The same form was also administered to a national equating sample. More information about the national equating samples used for equating is in Chapter 6 of the SAT Suite of Assessments Technical Manual (College Board, 2017). The target statistical specifications for the SAT Suite are in Appendix A. The target values for difficulty, discrimination, and reliability are summarized in Tables A1 to A5.

SAT Essay

Test takers opting to take the SAT Essay receive an additional 50 minutes at the end of the SAT testing session to compose a clear and cogent analysis of a high-quality source text. The same prompt appears with every essay text:

"As you read the passage below, consider how [the author] uses

- evidence, such as facts or examples, to support claims.
- reasoning to develop ideas and to connect claims and evidence.

- stylistic or persuasive elements, such as word choice or appeals to emotion, to add power to the ideas expressed.

Write an essay in which you explain how [the author] builds an argument to persuade [his/her] audience that [author's claim]. In your essay, analyze how [the author] uses one or more of the features listed above (or features of your own choice) to strengthen the logic and persuasiveness of [his/her] argument. Be sure that your analysis focuses on the most relevant features of the passage. Your essay should not explain whether you agree with [the author's] claims, but rather explain how the author builds an argument to persuade [his/her] audience." (College Board, N.D.)

Two readers score each essay, assigning a score from 1 to 4 to each of the Reading, Analysis, and Writing dimensions. Unscorable essays, such as those that are off-topic or written in a language other than English, receive a score of 0. The Reading score assesses the evidence in the essay that the test taker understood the passage, including the interplay of the main themes and the important details. The Analysis score reflects evidence in the essay that the test taker understands how the author builds an argument, including the author's use of evidence, reasoning, and persuasion. A high Writing score is given to essays that are focused, organized, and precise; that show a command of language, including the conventions of standard written English; and that have a variety of sentence structures and consistent, precise word choice.

For each dimension, the two rater scores are added to form the reported score. If one rater gives an essay a score of 0 or the two raters' scores differ by more than one point, a third rater scores the essay. The third rater's score is doubled to yield the reported score. If an essay receives a score of 0 on one dimension, then it is scored 0 on all three dimensions.

Characteristics of the March 2020 School Day Administration of the SAT in Delaware

Test Forms and Demographic Information

This report summarizes the data at the master form level for SAT form 1, form 2, form 3, form 4 and form 5. The master form was built with four timed sections (Reading, Writing and Language, Math - No Calculator, and Math - Calculator).

Along with the test questions, each test taker completed several survey and demographic questions, including gender, current grade level (Not yet in 8th grade; 8th grade; 9th grade; 10th grade; 11th grade; 12th grade or higher; No longer in high school; 1st year of college; 2nd year of college), ethnicity (Hispanic or Latino; Cuban; Mexican; Puerto Rican; Other Hispanic or Latino; or Not Hispanic or Latino) or race (American Indian or Alaska Native; Asian; Black or African American; Native Hawaiian or Other Pacific Islander; or White) and first language spoken (English only; English and another language; Another language). The race/ethnicity question was a two-part question worded in the following way:

What is your ethnicity? (You may mark more than one.)

- Hispanic or Latino (including Spanish origin)
- Cuban
- Mexican
- Puerto Rican
- Other Hispanic or Latino
- Not Hispanic or Latino

What is your race? (You may mark more than one.)

- American Indian or Alaska Native
- Asian (including Indian subcontinent and Philippines origin)
- Black or African American (including African and Afro-Caribbean origin)
- Native Hawaiian or Other Pacific Islander
- White (including Middle Eastern origin)

If a test taker selected more than one race, they were included in the Two or More Races category only.

Description of the Item Analysis Sample

Before completing the analyses contained in this report, the data used in these analyses were cleaned to exclude any test takers who were not included in the accountability file. See Table 3 for the frequency of test takers in the sample for this administration by grade level, first language, and gender. See Table 4 for the frequency of test takers in the target item analysis sample that responded to the race/ethnicity question. Note that due to COVID_19, the make-up for this administration was cancelled and some schools intending to test in this administration may not have been able to test.

Description of the Test Analyses

Moments and Score Distributions

Test taker performance is described using the first four moments for all score tiers. The mean, standard deviation, skewness, and kurtosis provide a description of the distribution of scores. Subgroup results are only reported for forms for which the subgroup sample size was 5 or more.

Intercorrelations

The Pearson product moment correlation coefficient provides an evaluation of the pairwise linear relationship between the total, section, test, and cross-test scores, and the subscores. The disattenuated, or true score correlations, are the correlations after correcting for unreliability in the two scores. Subgroup results are only reported for forms for which the subgroup sample size was 100 or more. The formulas for calculating the Pearson correlations and disattenuated, or true score, correlations are in Appendix B1 and B2, respectively.

Reliability and Standard Error of Measurement

Reliability is a measure of consistency in test takers' observed scores. Test takers' observed scores may vary for many reasons. This variance can occur, for example, if the test is administered at two different points in time, across different forms of a test, or due to changes in test administration or scoring conditions. There are many different methods to estimate reliability coefficients, including those based on Generalizability Theory, Classical Test Theory, and Structural Equation Modeling. For the SAT Suite, the compound binomial model is used to calculate reliability for scale scores (See Appendix B3). Reliability estimates range from 0-1, with values near 1 indicating more consistency and values near 0 indicating little to no consistency.

Standard error of measurement (SEM) can be considered a measure of inconsistency in test takers' observed scores. An SEM estimate measures the dispersion of measurement errors over repeated measures of a person on the same instrument. SEM estimates are inversely related to reliability estimates. An SEM value is an average across all observed scores while a conditional standard error of measurement (CSEM) is the estimated SEM for a particular (conditioned on) observed score. For the scores that were mathematically derived including Math Test, ERW, and Total scores, the root mean squared CSEM (RMS(CSEM)) was calculated.

Scale score reliability estimates were derived from averaging the CSEM values obtained from the Delaware March 2020 School Day administration. See Section 6.1 of the SAT Suite of Assessments Technical Manual for more details on the scale score reliability estimates. The formulas for calculating the scale score reliability and average CSEM estimates are in Appendix B3 of this document.

Standard error of difference (SED) is calculated to assess how much scores must differ in order to reflect the differences in student ability when comparing scores between students for the same measure. If two scores differ by at least SED times 1.65, it is unlikely that the two scores indicate that the two candidates are equal in ability, since this level difference would occur 10 percent of the time or less. The formula for SED is in Appendix B4.

See the Table 5 series for scale score observed and true score correlations, moments, reliability, and RMS(CSEM) and SED values for the total group, gender, and race/ethnicity subgroups for this administration. In the correlation tables, the values above the diagonal represent the true score correlations. The correlations below the diagonal represent the observed score correlations. Subgroup results are only reported for forms for which the subgroup sample size was 100 or more.

Item Completion Rates and Form Speededness

Item completion rates reflect the percentage of test takers reaching an item within each timed section. A reached item is one with a marked response. Conversely, a not reached item is one with no marked answer and no subsequent items with a marked answer within that timed section. Test form speededness is evaluated by examining the following:

- the number of items reached by at least 80% of the test takers
- the percentage of test takers completing at least 75% and 90% of each timed section
- the mean and standard deviation of the number of items not reached

Seventy-five (ninety) percent of a timed section is determined by the ceiling of 75% (90%) of the section length. For example, if a section has 47 items, the statistic is calculated as the percentage of test takers completing 36 or more items in the section. The degree of speededness of a test is negligible when 80% of the students reach the last item and all students reach at least 75% of the items (van der Linden, 2011). However, judgments of appropriateness of timing should be made using all relevant data. See Tables 6 and 7 for the speededness statistics for this administration. Subgroup results are only reported for forms for which the subgroup sample size was 5 or more.

Differential Item Functioning

Differential item functioning (DIF) is a statistical method that examines the performance of reference and focal subgroups for possible statistical bias. Based on the formulas from Dorans and Holland (1993), found in Appendix B5, the Mantel-Haenszel D-DIF (MH D-DIF) statistic is calculated. MH D-DIF values that are not statistically different from zero are classified as *A* items. Items with a p-value that exceeds 1.96 in absolute value and are significantly larger than 1.5 or less than -1.5 are classified as *C* items. The remaining values are classified as *B* items.

For analysis of DIF for gender, the performance of males is compared to the performance of females, with males serving as the reference group and females as the focal group. For analysis of DIF for racial/ethnic group, the performance of White test takers as the reference group is compared to other racial/ethnic focal subgroups. Ethnicity is defined as Hispanic or non-Hispanic and race is defined as American Indian or Alaska Native (AIAN), Asian, Black or African American, Two or More Races, and White. All non-Hispanic respondents are identified as one of the previously listed race categories with Native Hawaiian or Other Pacific Islander classified as Asian. If a test taker selected more than one race, they were included in the Two or More Races category only. DIF analysis for a specific group for an item is only completed if the sample sizes for the item are 200 for the focal group and 500 in total. The final DIF category for the item was determined by the worst DIF category compared across gender and race/ethnicity DIF categories. See Table 8 for the summary of DIF values across the test forms.

Standardized Differences Between Groups

The test taker performance for each subgroup is described using the mean and standard deviation for all score tiers and the standardized mean differences between the focal and reference groups. See Appendix B6 for the formula for the standardized mean difference. Cohen (1988) suggests standardized mean differences equal to 0.20 are small, 0.50 are medium, and 0.80 are large. See the Table 9 series for the standardized mean differences between subgroups with sample sizes of 100 or more for this administration.

Classification Levels

Classification levels are based on ERW and Math Section cut scores that were determined by state leadership based on recommendations from panelists during a multi-state standard setting held in June 2016 (Morgan, Sweeney, Reshetar, Patel, & McCullough, 2016). The cut scores from the standard setting suggest test takers can be classified into four performance levels with level one being the lowest and level four being the highest. Test takers with an ERW score of at least 480 are considered proficient. Test takers with a MSS score of at least 530 are considered proficient.

Upon the establishment of classification levels, one may also examine classification statistics (e.g., classification accuracy and classification consistency). Classification accuracy is the agreement between classifications based on the estimated true scores and observed scores. Classification consistency is the agreement between the classification of expected scores and actual observed scores. The classification accuracy and classification consistency decisions are from calculations using the BB-CLASS software (Brennan, 2004). The classification statistics are based on the Livingston & Lewis (1995) method which uses a four-parameter beta-binomial model with effective test length. This method is particularly useful for calculating classification accuracy of composite scores, like ERW. See Appendixes B7 – B14 for the formulas related to classification accuracy and classification consistency. Subgroup results are only reported for forms for which the subgroup sample size was 100 or more. See Tables 10-12 for the classification statistics results.

Description of the SAT Essay Analyses

Description of the Sample

This report summarizes the essay results associated with the SAT master forms administered in March 2020. Two prompts were administered in the March 2020 SAT Essay test; this report summarizes data at the overall level (i.e., aggregating across all forms and all prompts) and select results are also summarized at the prompt level for prompts with 5 or more test takers.

A score of 0 is assigned to unscorable essays, so a score of 0 is excluded in all of the analyses in this report (e.g., Moments, correlation, and interrater reliability analyses), except for the frequency distributions of scores (including all three dimensions).

Moments and Score Distributions

Test taker performance is described using descriptive statistics (i.e., mean, standard deviation, skewness, and kurtosis) and frequency distributions of scores for all three essay dimension scores. All observed combinations of the three essay dimension scores (512 possible combinations for three dimension scores), along with the frequency and percentage of occurrence provide full information on the joint distribution of the three essay dimension scores. See the Table 13 series for the essay score moments and the Table 14-17 series for the frequency distributions, aggregated across prompts and by prompt. In these tables, the term "Rater Set" refers to an aggregation of scores across all raters assigned as the first or second rater for a particular essay. In addition, the set of raters may not necessarily be unique.

Intercorrelations

The Pearson product moment correlation coefficient provides an evaluation of the pairwise linear relationship between two essay scores or between essay scores and ERW section, Reading Test, and Writing and Language Test scores. The formula for calculating the Pearson correlations is in Appendix B1. See Table 18 for the correlations between essay dimension scores. See Table 19 for the correlations between the essay dimension and relevant ERW section, Reading Test, and Writing and Language Test scores.

Reliability and Standard Error of Measurement

As described previously, reliability refers to the consistency with which an instrument measures some attribute of a person or object. In the context of these analyses, reliability refers to the consistency of test takers' observed scores on the essay dimension scores, given no change in actual ability. There are many reasons a person may score higher or lower on the essay test on any given day. These include situational variables, the particular passage associated with the essay, rater fluctuations, and a number of other factors. If we consider these fluctuations in scores to be errors, then reliability is an index of the proportion of the measurement that is not an error. Reliability estimates range from 0 to 1, with reliability estimates near 1 indicating consistent measurement with very little error. Reliability estimates near zero, on the other hand, would indicate fairly random estimates of the attribute. See Appendixes B15-B20 for formulas related to essay reliability, variance, and SEM.

Percentages of Agreement

Percentage of exact agreement is an index of interrater agreement. It can be expressed as the number of agreements divided by the total observations (see Appendix B15 for the formula). For ordinal and interval data, percentages of close-but-not-exact agreement (e.g., percentage of adjacent scores – where raters differ by 1 score point) can also be computed and, along with percentage of exact agreement, used as measures of interrater agreement. The percentage of exact agreement does not take into account agreements due to chance. Therefore, it overestimates the level of agreement (Hallgren, 2012). Percentage of exact agreement results are presented in the Table 20 series and in Table 21.

Correlation Coefficient and Standard Error of Measurement

The correlation coefficient between the scores given by two raters on the same essay dimension scores is another measure of interrater consistency. Interrater reliability is the reliability of a single rater scoring the essay. This reliability estimate focuses on the stability of the essay scores across raters: How much would the results differ if two different raters were to score the same essay for a test taker? Although the reliability coefficient corresponds to a single rater, the estimation of interrater reliability requires that at least two raters score the same essay for the same test taker, so the reliability of the raters can be estimated. The formulas for computing the Pearson correlation coefficient and related statistics are in Appendixes B1 and B16-18. See Table 22 for the correlation and SEM values for two raters for the essay dimension scores.

Simple Kappa Statistic

Cohen's kappa coefficient (simple kappa statistic; Cohen, 1960) is a statistic that measures the interrater agreement between two raters. It computes the observed level of agreement between two raters, while taking into account the possibility of agreement occurring by chance. The observed agreement is defined by cross-tabulating the scores of the two raters, and the agreement expected by chance is defined by the marginal frequencies of each rater's score. The formula for calculating Cohen's kappa coefficient is given in Appendix B19. Possible values for Cohen's kappa coefficient range from -1 to 1, with 1 indicating complete agreement, 0 indicating complete random agreement, and -1 indicating complete disagreement.

Weighted Kappa Statistic

Weighted kappa coefficient (Cohen, 1968) is an alternative statistic that measures the interrater agreement between two raters, while correcting for the possibility of agreement by chance and penalizing the disagreements. This statistic can be applied to ordinal ratings. The weights used to penalize the disagreement are computed based on the magnitude of disagreement. The formula for calculating weighted kappa coefficient is given in Appendix B20. Possible values for weighted kappa coefficient range from -1 to 1, with 1 indicating complete agreement, 0 indicating complete random agreement, and -1 indicating complete disagreement.

See Table 23 for simple and weighted kappa coefficients for the essay dimension scores.

Standardized Differences Between Groups

See the Table 24 series for the standardized mean essay dimension score differences between the reference and focal subgroups for this administration.

Appendix A: Target Specifications for the SAT Suite of Assessments

The target statistical specifications for the SAT Suite of Assessments describe the desired distribution or range of values on the assessment in terms of item difficulty, item discrimination, and overall reliability. Tables A1 - A3 outline exactly how many items are included at each difficulty level (i.e., easy, medium, hard). The bounds for item difficulty levels are based on historical data. The current difficulty classifications based on p-values are used in combination with the target statistical specifications to identify the number of items per difficulty classification for each score tier.

Table A1. Target Number of Items per Difficulty Classification by Reading and Writing and Language Test Scores and Subscores

Score and difficulty level	Number of Items
Reading	
Hard ($.03 \leq p \leq .45$)	19
Medium ($.46 \leq p \leq .81$)	18
Easy ($p \geq .82$)	15
Writing and Language

Passport to Advanced Mathematics	0.743	0.809

Appendix B: Test Analysis Formulas

B1. Pearson Product Moment Correlation Coefficient

$$\rho_{XY} = \frac{\sum Z_X Z_Y}{N},$$

where Z_X and Z_Y represent z-scores of observed scores X and Y , respectively, and N represents the number of test takers (Crocker & Algina, 1986).

B2. Disattenuated Correlations/True Score Correlations

$$\rho_T = \frac{\rho_{XY}}{\sqrt{SA_X SA_Y}},$$

where ρ_{XY} is the correlation between observed scores X and Y , and SA_X and SA_Y represent the stratified alpha reliability of score X and Y , respectively (Schumacker & Muchinsky, 1996).

B3. Scale-score CSEM and Reliability Estimates

The reliabilities for scale scores were estimated from the average CSEM using the following equation:

$$Reliability_{SC} = 1 - \frac{MS(CSEM)_{SC}}{SD_{SC}^2}, \text{ where}$$

SD_{SC}^2 is the variance of scale score. The mean squared CSEM, $MS(CSEM)$ was obtained as the weighted average of the squared CSEMs for the scales directly established. Thus, the $MS(CSEM)$ can be written as

$$MS(CSEM)_{SC} = \int CSEM_{SC(\tau)}^2 Prob(\tau) d\tau, \text{ where}$$

$CSEM_{SC(\tau)}^2$ is the squared scale score CSEM at the true score, τ , and the average of these is obtained over the probability distribution of τ , $Prob(\tau)$.

For the scores that were mathematically derived including Math Test, ERW, and Total scores, the following equations were used to compute the root mean squared CSEM, $RMS(CSEM)$:

$$RMS(CSEM)_{MTS} = \sqrt{\frac{MS(CSEM)_{MSS}}{20^2}},$$

$$RMS(CSEM)_{ERW} = \sqrt{MS(CSEM)_R \cdot 10^2 + MS(CSEM)_{WL} \cdot 10^2},$$

$$RMS(CSEM)_{Total} = \sqrt{MS(CSEM)_{ERW} + MS(CSEM)_{MSS}}.$$

B4. Standard Error of the Difference

The formula for computing the Standard Error of the Difference (SED) is:

$$SED = \sqrt{2 * SEM^2},$$

where it is assumed that scores of two students would be independent with equal SEMs across testing times, so that the variance of the score difference could be estimated by doubling the squared SEM.

When comparing scores between students for the same measure (Reading, Writing, Math), the standard error of the difference (SED) can be used to assess how much scores must differ in order to reflect true differences in ability. If two scores differ by at least SED times 1.65, it is unlikely that the two scores indicate that the two candidates are equal in ability since this level difference would occur 10 percent of the time or less. For example, when the SED is 40 points, you can be reasonably confident that if the score difference between two test-takers is greater than 66 points (40×1.65), the two test-takers are not likely to be equal in true ability.

B5. Mantel-Haenszel D-DIF Statistic

Based on the formulas from Dorans and Holland (1993), the Mantel-Haenszel D-DIF (MH D-DIF) statistics is calculated for subgroups of gender and ethnicity/race with the following formula:

$$MH\ D - DIF = -2.35 \ln[\alpha_{MH}],$$

where α_{MH} is an estimate of the odds ratio. "Positive values of MH D-DIF favor the focal group, whereas, negative values favor the reference group" (Dorans & Holland, 1993, p 41). The odds ratio is calculated as

$$\alpha_{MH} = \frac{\sum_m R_{rm} \frac{W_{fm}}{N_{tm}}}{\sum_m R_{fm} \frac{W_{rm}}{N_{tm}}},$$

where R_{rm} is the number correct in reference group at ability level m , W_{fm} is the number incorrect in the focal group at ability level m , N_{tm} is the number in total group at ability level m , R_{fm} is the number correct in the focal group at ability level m , and W_{rm} is the number incorrect in the reference group at ability level m . At the test development stage, the minimum sample size requirement for the focal group is 100 when calculating the statistics.

B6. Standardized Mean Difference

The formula for computing a standardized mean difference is:

$$Std.\ Diff.\ = \frac{\bar{X}_f - \bar{X}_r}{SD_{X,P}},$$

where \bar{X}_f and \bar{X}_r represent mean scores for the focal group and reference group (white or male), respectively, and $SD_{X,P}$ represents the total group (pooled) standard deviation (Cohen, 1988):

$$SD_{X,P} = \sqrt{\frac{(n_f - 1)SD_{X_f}^2 + (n_r - 1)SD_{X_r}^2}{n_f + n_r - 2}},$$

where n_f and n_r represent sample sizes for the focal group and reference group, respectively, and $SD_{X_f}^2$ and $SD_{X_r}^2$ represent standard deviations for the focal group and reference group, respectively (Cohen, 1988).

B7. False Positive Rate

The formula for computing the false positive rate is:

$$R_{fp} = \int_0^{\tau_0} \Pr(X \geq x_0 | \tau) g(\tau) d\tau,$$

where τ_0 is the true score, x_0 is the raw score cut point, X is the raw score obtained by a randomly selected test-taker, $g(\tau)$ is the true score density, which is obtained using the four-parameter beta-binomial model with effective test length (Brennan, 2004; Livingston & Lewis, 1995 ; Hanson & Brennan, 1990).

B8. False Negative Rate

The formula for computing the false negative rate is:

$$R_{fn} = \int_{\tau_0}^1 \Pr(X \leq x_0 - 1 | \tau) g(\tau) d\tau,$$

where τ_0 is the true score, x_0 is the raw score cut point, X is the raw score obtained by a randomly selected test-taker, $g(\tau)$ is the true score density, which is obtained using the four-parameter beta-binomial model with effective test length (Brennan, 2004; Livingston & Lewis, 1995 ; Hanson & Brennan, 1990).

B9. Probability of Correct Classification

The formula for computing the probability of correct classification is:

$$P = 1 - R_{fp} - R_{fn},$$

where R_{fp} is the false positive rate and R_{fn} is the false negative rate.

B10. Effective Test Length

The formula for effective test length is:

$$\tilde{n} = \frac{(\mu_x - X_{min})(X_{max} - \mu_x) - r\sigma_x^2}{\sigma_x^2(1 - r)},$$

where X_{min} is the lowest score for raw score X , X_{max} is the highest score, μ_x is the mean, σ_x^2 is the variance, and r is the reliability (Brennan, 2004; Livingston & Lewis, 1995).

B11. Proportion of Consistent Decisions

The formula for computing the proportion of consistent decisions is:

$$p = \Pr(X_1 \leq x_0 - 1, X_2 \leq x_0 - 1) + \Pr(X_1 \geq x_0, X_2 \geq x_0),$$

where X_1 and X_2 are raw score random variables for two independent administrations and x_0 is the raw score cut point (Brennan, 2004; Livingston & Lewis, 1995; Hanson & Brennan, 1990).

B12. Proportion of Consistent Decisions by Chance

The formula for computing the proportion of consistent decisions by chance is:

$$p_c = \Pr(X_1 \leq x_0 - 1) \Pr(X_2 \leq x_0 - 1) + \Pr(X_1 \geq x_0) \Pr(X_2 \geq x_0),$$

where X_1 and X_2 are raw score random variables for two independent administrations and x_0 is the raw score cut point (Brennan, 2004; Livingston & Lewis, 1995; Hanson & Brennan, 1990).

B13. Kappa Statistic

The formula for computing the kappa statistic is:

$$k = \frac{p - p_c}{1 - p_c},$$

where p is the proportion of consistent decisions and p_c is the proportion of consistent decisions by chance (Brennan, 2004; Livingston & Lewis, 1995; Hanson & Brennan, 1990).

B14. Probability of Misclassification

The formula for computing the probability of misclassification is:

$$p_m = 1 - p,$$

where p is the proportion of consistent decisions.

B15. Percentage of Exact Agreement

The percentage of exact agreement (in percentage) is computed as

$$p = \sum p_{ij} \text{ for all } i = j.$$

B16. Single-Rater Reliability Coefficient

The single-rater reliability coefficient $\rho_{RR'}$ for a given dimension is estimated by the Pearson correlation between the first and second rater scores.

B17. Single-Rater Variance

The single-rater variance σ_R^2 for a dimension score or for the sum of dimension scores can be computed on either the first or second rater scores. Because both rater scores are generated from the same pool of raters, the two estimates are equivalent. In these analyses, the single-rater variance is estimated using the arithmetic average of the variances of the first and second rater scores:

$$\sigma_R^2 = \frac{1}{2} (\sigma_{R1}^2 + \sigma_{R2}^2).$$

B18. Single-Rater Standard Error of Measurement

The variance error of measurement for a single rater SEM_R is given by:

$$SEM_R = \sqrt{(1 - \rho_{RR'})\sigma_R^2}.$$

B19. Simple Kappa Coefficient

The simple kappa coefficient is given by

$$\hat{\kappa} = (p_0 - p_e) / (1 - p_e),$$

where p_0 is the observed probability of agreement and is computed as $p_0 = \sum p_{ij}$ for all $i=j$. p_e is the expected probability of agreement and is computed as $p_e = \sum p_i \cdot p_j$ for all $i=j$.

The asymptotic variance of the simple kappa coefficient is computed as

$$\text{var}(\hat{\kappa}) = \frac{\sum_{i=j} \left(p_{ij} \left(1 - (p_{i.} + p_{.j}) (1 - \hat{\kappa}) \right)^2 \right) + (1 - \hat{\kappa})^2 \sum \sum_{i \neq j} \left(p_{ij} (p_{i.} + p_{.j})^2 \right) + (\hat{\kappa} - p_e (1 - \hat{\kappa}))^2}{(1 - p_e)^2 * n}.$$

The asymptotic standard error (ASE) is the square root of the asymptotic variance. The confidence limits are computed as

$$\kappa \pm (1.96 * \sqrt{\text{var}(\hat{\kappa})})$$

B20. Weighted Kappa Coefficient

The weighted Kappa coefficient is a generalization of the simple Kappa coefficient that uses the weights to quantify the relative difference between categories. It is computed as

$$\hat{k}_w = \left(p_{0(w)} - p_{e(w)} \right) / \left(1 - p_{e(w)} \right),$$

where p_0 is the observed probability agreement and is computed as $p_{0(w)} = \sum_i \sum_j w_{ij} p_{ij}$ and $p_{e(w)}$ is the expected probability agreement and is computed as $p_{e(w)} = \sum_i \sum_j w_{ij} p_i p_j$. The weights, w_{ij} , are constructed so that $w_{ij}=1$ for all $i=j$, $0=w_{ij}<1$ for all $i=j$, and $w_{ij}=w_{ji}$. The asymptotic variance of the weighted kappa coefficient is computed as

$$\text{var}(\hat{k}_w) = \frac{\sum_i \sum_j p_{ij} \left(w_{ij} - \left(\sum_j p_{.j} w_{ij} + \sum_i p_{i.} w_{ij} \right) \left(1 - \hat{k}_w \right) \right)^2 - \left(\hat{k}_w - p_{e(w)} \left(1 - \hat{k}_w \right) \right)^2}{\left(1 - p_{e(w)} \right)^2 * n}.$$

The asymptotic standard error (ASE) is the square root of the asymptotic variance. The confidence limits are computed as

$$\hat{k}_w \pm \left(1.96 * \sqrt{\text{var}(\hat{k}_w)} \right).$$

B21. Criterion-Referenced Reliability Coefficient

The criterion-reference reliability coefficient is computed as:

$$k^2(X, T_x) = \frac{\rho^2(X, T_x) \sigma^2(X) + (\mu_x - C_x)^2}{\sigma^2(X) + (\mu_x - C_x)^2},$$

where μ_x is the mean, $\sigma^2(X)$ is the variance, $\rho^2(X, T_x)$ is the norm-reference reliability, and C_x is the criterion score.

About the College Board

The College Board is a mission-driven, not-for-profit organization that connects students to college success and opportunity. Founded in 1900, the College Board was created to expand access to higher education. Today, the membership association is made up of over 6,000 of the world's leading educational institutions and is dedicated to promoting excellence and equity in education. Each year, the College Board helps more than seven million students prepare for a successful transition to college through programs and services in college readiness and college success — including the SAT® and the Advanced Placement Program®. The organization also serves the education community through research and advocacy on behalf of students, educators, and schools. For further information, visit www.collegeboard.org.
