Lesson Outline for Teaching

Lesson 3: Biological Evidence of Evolution

- **A.** Evidence for Evolution
 - **1.** Evolution does not occur in a straight line with one species <u>replacing</u> another in a series of orderly steps.
 - a. Living species that are closely related share a common ancestor.
 - **b.** How closely related two species are depends when they <u>diverged</u>, or split, from their common ancestor.
 - **2.** The study of similarities and differences among structures of living species is called comparative anatomy.
 - **a.** Body parts of organisms that are similar in position but different in function are called <u>homologous structures</u>. The forelimbs of different mammals are examples.
 - **b.** If species have homologous structures, this suggests that the species are <u>related</u>.
 - **c.** The more similar two structures are to each other, the more likely it is that the species have evolved from a recent <u>common ancestor</u>.
 - **d.** <u>Analogous structures</u> are body parts that perform a similar function but differ in structure. The wings of flies and birds are examples.
 - **e.** The existence of analogous structures indicates that the species are not <u>closely</u> related.
 - **3.** Body parts that have lost their original function through evolution are called <u>vestigial structures</u>. The <u>wings</u> of flightless birds are an example.
 - **a.** The best explanation for <u>vestigial structures</u> is that the species that have vestigial structures are <u>related</u> to ancestral species that still use the structures for a specific purpose.
 - **b.** Whales have a tiny <u>pelvic</u> bone, which is a vestigial structure for walking on land.
 - **4.** Studying the development of <u>embryos</u> can also provide scientists with evidence that certain species are related.
 - **a.** <u>Embryology</u> is the study of the development of embryos from fertilization to birth.
 - **b.** All species of <u>vertebrates</u> have pharyngeal pouches at some stage during their development.
 - **c.** The similarities in location and function of the <u>pharyngeal pouches</u> is a sign that the vertebrate species share a common ancestor.

Lesson Outline continued

- **5.** The study of gene structure and function is called <u>molecular biology</u>.
 - **a.** The existence of <u>genes</u> provides evidence of evolution because they have been shown to be the source of variation upon which <u>natural selection</u> acts.
 - **b.** The more closely related two species are, the more similar their <u>genes</u> and <u>proteins</u> are.
 - **c.** Studies in molecular biology have shown that some stretches of <u>DNA</u> that are common to many species change through time at steady, predictable rates like a kind of molecular clock.
 - **d.** Scientists use this molecular clock to estimate the time in the past when living species <u>diverged</u> from common ancestors.
- **B.** The Study of Evolution Today
 - **1.** Since the publication of Darwin's theory, scientists have <u>confirmed</u>, refined, and extended his work.
 - **2.** Scientific studies of fossils, anatomy, embryology, and molecular biology have provided evidence of relatedness among <u>living</u> and <u>extinct</u> species.
 - **3.** The continuous discovery of new <u>fossils</u> that have features of species that lived before and after them is strong evidence of evolution of species.
 - **4.** Scientists today are studying how genes can be reorganized in simple ways that cause dramatic changes in organisms.
 - **5.** Though scientists now study evolution at the <u>molecular</u> level, the basic principles of Darwin's theory of evolution by natural selection have remained unchanged for more than <u>150</u> years.

Discussion Question

How could studying the genetic sequence of a dinosaur's DNA provide further evidence of biological evolution?

It might give clues about the ancestor of that species of dinosaur or about the ancestor of dinosaurs in general; it might give clues about which species, if any, arose directly from that dinosaur species or which modern species are most closely related to that dinosaur species.
