

## Charge and Electricity

### Electric Charge

*Charge is a fundamental property of matter, like mass.  
 Objects are either positive, negative, or neutral.*

Electric charges work like magnetic poles:

*Charges can only move because of electrical forces.*

*The unit of electric charge is the coulomb.*

**Electrical forces are very strong!**  
 If 1 negative coulomb were 1 meter away from 1 positive coulomb the force would be 9 billion newtons! Yes, **9,000,000,000 N**! This is how strong the forces are that hold molecules (and you) together.

### Charges come from within the atom

**Electrical forces cause electrons to move.**

*Electricity is moving electrons.*

Moving electrons cause electricity.

### Net Charge

$$p - e = \text{charge}$$

(# of protons - # electrons = net charge)

#### A Sodium Ion: $\text{Na}^{1+}$

11 protons  
 10 electrons  
 $p - e = \text{charge}$   
 $11 - 10 = 1$   
**Net charge = +1**

Any atom that is not neutral we call an **ion**. Positive ions are called **cations**. Negative ions are called **anions**. Metals tend to become cations; non-metals tend to become anions. Cations attract anions and become **neutral ionic compounds**.

Positive sodium ions ( $\text{Na}^{1+}$ ) attract negative chlorine atoms ( $\text{Cl}^{1-}$ ) to make the **ionic compound** of NaCl: sodium chloride, table salt.

Lightening is a huge build up of **static electricity** in the clouds, just like when you drag your feet across a carpet. When enough charge is

built up to break through the air (ionizing it), lightening occurs, releasing the charge. You discharge static electricity when you touch a doorknob.

***Charged objects try to discharge because all objects want to be electrically neutral.***

### Ionic Notation

Two easy steps:

1) Give the element symbol (found from number of protons). 11 protons is "sodium", or "Na".

11 protons; 10 electrons

2) Put the charge in the upper right corner (from  $p - e = \text{charge}$  and  $11 - 10 = +1$ )

This ion notation tells us a sodium atom (11 protons) lost 1 electron (10 electrons) to become a positive ion.

*Example: Give the ion notation for an atom with 8 protons and 10 electrons.*

Protons: 8  
 Element: Oxygen (O)  
 Charge:  $p - e = \text{charge}$   
 $8 - 10 = -2$

Ionic notation:

**Conductors versus Insulators****Conductors of electricity also conduct heat, thermal energy.**

**Conductors allow electricity to flow.** Metals tend to be excellent conductors.

**Insulators resist the flow of electricity.** Conductors tend to be light or have “air holes”.

**Conductors tend to feel cold** because they accept your heat easier.

Electrical wires have a metal center to conduct electricity surrounded by insulation for protection.

Pure water is a poor conductor: good for drinking, not so good for heat conduction. Sports drinks add salts and salt water is a very good thermal conductor.

1. Insulator 2. Conductor 3. Positive 4. Negative 5. Electricity 6. Ion	A. The charge that attracts protons. B. An atom with a different number of electrons than protons. C. A material that resists the flow of electricity. D. The caused by the flow of electrons. E. The charge that attracts electrons. F. A material that does not resist electricity.	1. Electric charge 2. Static electricity 3. Electrical force 4. Coulomb 5. Electrically neutral	A. A unit in measuring the amount of charge B. The pushes and pulls that electric charges exert on each other C. Property of matter responsible for electrical events; it has two forms, positive and negative. D. An object that has equal amounts of positive and negative charges. E. A buildup of charge on an object.
What are the charges of the second objects? <div style="text-align: center; margin-top: 10px;"> <span style="margin: 0 20px;"> <i>attracting</i>  </span> <span style="margin: 0 20px;"> <i>repelling</i>  </span> </div>		An atom that loses electrons becomes positive/negative. An atom that gains electrons becomes positive/negative.	
<b>Insulator or <u>C</u>onductor?</b>			
<div style="display: flex; flex-wrap: wrap;"> <div style="width: 33%; text-align: center;">___ Silver</div> <div style="width: 33%; text-align: center;">___ Glass</div> <div style="width: 33%; text-align: center;">___ Gold</div> <div style="width: 33%; text-align: center;">___ Wood</div> <div style="width: 33%; text-align: center;">___ Copper</div> <div style="width: 33%; text-align: center;">___ Styrofoam</div> <div style="width: 33%; text-align: center;">___ Air</div> <div style="width: 33%; text-align: center;">___ Pure water</div> <div style="width: 33%; text-align: center;">___ Aluminum</div> </div>			
Label the parts of the object as conductor or insulator. <div style="margin-top: 20px;">           A. _____  B. _____         </div>		<div style="display: flex; align-items: center;"> <div>             Protons:              Electrons:              Net Charge:              Neutral or Ion?              (Cation or Anion)              Ion Notation:              (symbol) → _____           </div> </div>	
After you rub a balloon on your hair it might stick to a wall. Why? Be specific.		<div style="display: flex; align-items: center;"> <div>             Protons:              Electrons:              Net Charge:              Neutral or Ion?              (Cation or Anion)              Ion Notation:           </div> </div> <p style="margin-top: 20px;">What would happen if this atom were brought close to the atom above it?</p>
