

Mini-Lab: Boiling Substances - Part II

In part I you created a heating curve to apply Module 1 content. We will now apply Module 2 content to the information from this lab.

Number your responses to the following on the right hand page. Show all set up and work for calculations

1. When a substance reaches its boiling point, added heat will no longer raise the temperature of the liquid. Based on this, what is the boiling point of each substance according to your data?
2. The accepted boiling points of ethanol and water are 78.37°C and 100.00°C respectively. Choose one and calculate your percent error (show all work!)
3. The specific heat (c) of water is 4.184 J/g°C. Use $q = mc\Delta T$ to determine how much energy (q) was required to bring your water from room temperature to its boiling point (for mass (m), remember that the density of water is 1.00g/mL)

Challenge! Determine the specific heat of ethanol (optional)

- A • Divide your answer from #4 by the time required for the water to reach its boiling point. This is the energy output of your specific hotplate during the experiment in J/s. Multiply this number by the time required to boil ethanol to find the heat absorbed by the ethanol during that time (q)
- B • The density of ethanol is 0.789g/mL. Use this information to find the mass of 35.0 mL of ethanol
- C • Use $q = mc\Delta T$ to solve for the specific heat (c) of ethanol

$$\textcircled{A} 11300 \text{ J} / 600.5 = 18.8 \text{ J/s}$$

$$\frac{270\text{s} | 18.8 \text{ J}}{\text{s}} = \boxed{5080 \text{ J}} \leftarrow \text{energy to boil ethanol (q)}$$

$$\textcircled{B} \frac{35.0 \text{ mL} | 0.789 \text{ g}}{\text{mL}} = 27.6 \text{ g} \leftarrow \text{mass of ethanol}$$

$$\textcircled{C} c = \frac{q}{m\Delta T} \leftarrow \text{rearrange first!}$$

$$c = \frac{5080 \text{ J}}{(27.6 \text{ g})(79^\circ\text{C} - 22^\circ\text{C})} = \boxed{3.23 \text{ J/g}^\circ\text{C}}$$

\leftarrow accepted is 2.46 J/g°C, so we had a pretty large % error (31%)

① will vary depending on class period & group

$$\textcircled{2} \% \text{Error} = \frac{|\text{accepted} - \text{experimental}|}{\text{accepted}} \times 100$$

example (posted data):

$$\text{BP}_{\text{ethanol}} = 79.4^\circ\text{C}$$

$$\frac{|78.37^\circ\text{C} - 79.4^\circ\text{C}|}{78.37^\circ\text{C}} \times 100 = \boxed{1.31\%}$$

$$\begin{aligned} \textcircled{3} \text{ Known: } m &= 35.0 \text{ g} \\ c &= 4.184 \text{ J/g}^\circ\text{C} \\ \Delta T &= 199.2^\circ\text{C} - 22.0^\circ\text{C} \\ &= 77.2^\circ\text{C} \\ q &= (35.0 \text{ g}) \left(\frac{4.184 \text{ J}}{\text{g}^\circ\text{C}} \right) (77.2^\circ\text{C}) \\ &= \boxed{11300 \text{ J}} \end{aligned}$$
