Mariana Trench: The Deepest Depths

By Becky Oskin, Contributing Writer | December 6, 2017 08:52am ET

G-MS
Global MAPPER

At 36,070 feet (10,994 m) deep, the Mariana Trench is the deepest part of the world's ocean. Commonly known as the Challenger Deep, the trench is a crescent-shaped scar in the Pacific Ocean floor, about 1,580 miles (2,540 km) long and 43 miles (69 km) wide. The trench's lowest point is the deepest place on the Earth's crust, a fact that has drawn explorers to the trench since the first sounding in 1875. The Challenger Deep is also the closest point on Earth to the center of the Earth. Because the Earth bulges at the equator, the Challenger Deep is 7 miles (11 km) farther from the center of the Earth than the summit of Mount Everest, the tallest mountain above sea level.

LIMITED-TIME OFFERS

The Challenger Deep is a long, narrow depression in the Mariana Trench, part of a subduction zone, where the Pacific Plate dives beneath the Philippine Plate. At a subduction zone, the oceanic crust is pushed and pulled downward into the mantle, the layer of rock between Earth's crust and its core. Where the two pieces of crust intersect, a deep trench forms. The Pacific Plate is sinking beneath the Philippine Plate at a rate of 2 inches (5 cm) per year, according to the Global Positioning System (GPS).

The Pacific crust, also called a tectonic plate, is one piece of the outermost shell of the Earth, which is broken into seven major plates and many minor ones. The Philippine plate is one of the minor plates.

The Mariana Trench is 1,580 miles (2,542 km) long, making it the longest trench on the western length of the Ranger Canyon. However, the deepest point is not in the middle of the trench, but toward the southern end.

The crushing water pressure on the floor of the Challenger Deep is more than 1,000 times the earth's 1,050 kilograms per square meter. That's like balancing the weight of 50 jumbo jets on the tip of a pencil.

How the trench formed

Earth's outermost shell, the rocky crust, is divided into pieces in a subduction zone, where the Pacific Plate is sinking beneath the Philippine Plate. At a subduction zone, oceanic crust is pushed and pulled downward into the mantle, the layer of rock between Earth's crust and its core. Where the two pieces of crust intersect, a deep trench forms. The Pacific Plate is sinking beneath the Philippine Plate at a rate of 2 inches (5 cm) per year, according to the Global Positioning System (GPS).

Life in the trench

Recent scientific expeditions have discovered unusual volcanoes in the Mariana Trench. Scientists found mud volcanoes on the deepest parts of the Mariana Trench's seven major valleys, or canyons, and on the deepest part of the trench's outer slope, which is the seaward side of the trench.

Food in the Mariana Trench is extremely scarce, and the trench is home to only a few species. Lewers, cucumbers and mines swim by the bottom, and amphipods, a type of crustacean, are common. Microbes that live on the surface must drop thousands of feet to reach the trench floor, and the few that survive are consumed by amphipods, mollusks, worms or sulfur, some other creatures.

Life is also found in the sediment on the floor of the trench. Scientists have found microbes at the bottom of the Mariana Trench and in sediment samples collected from the trench's seven major valleys.

The single-celled sarcophagines resemble amoebas, which live in soil, fresh water and absorbing their food. Amphipods are found in the trench's deepest valleys, and xenophyophores, which are single-celled foraminifera, may be a new species of sarcophagine.

"These are some of the deepest xenophyophores ever recorded," Glover said in a statement.

Scientists have also identified more than 90 species of bacteria in sediment samples from the Challenger Deep. The most common bacteria in the deepest sediments are Gammaproteobacteria, which can help eliminate the crushing cold and pressure of the Mariana Trench.

Exploring the trench

During Cameron's 2012 expedition, researchers collected more than 68 cubic feet (2 cubic meters) of sediment, crustaceans and other creatures, including shrimp-like amphipods and sea cucumbers, as well as video and photographs of the trench's unique environments. The Mariana Trench is home to only a few species, such as sea cucumbers, sea anemones, sea urchins, sea stars, sea urchins, sea cucumbers, sea urchins, sea cucumbers, sea urchins, sea cucumbers
